Using integrated non-survey data for monitoring and  
intervening in survey data collection

## RS7: Data Integration

# Different types of survey design

Survey designs produce data

Standardised survey  
design

Everyone in the sample treated the same

Adaptive survey designs

Sample treated differently depending on  
characteristics

# Why adaptive survey design?

Precipitous decline in response rates in recent years

Costs and budgetary pressures have also increased

Adaptive designs optimise data quality against cost

Target sub-groups in the sample

# Two types of adaptive design

## Targeted survey design

Static approach that involves a planning phase where decisions regarding targeting and interventions occur (Lynn 2017)

## Responsive survey design

Approach changes between phases of data collection using the data collected on non-response (Brick and Tourangeau 2017)

# Goals of adaptive design

Aims

Maximise data quality

Keep costs low

How

Targeting and intervention

Budgetary restraints

Requirements

Auxiliary data and process  
methodology

Some form of optimisation  
process

# Key definitions and jargon

## Targeting, strata and the problem

- Targeting is the identification of subgroups in the sample
- Subgroups are called strata
- The problem is the difference in response rates across strata

## Intervention, treatment and dosage

- Intervention is the differential in data collection applied to a stratum
- This is also called a treatment
- Dosage is the extent to which this treatment is applied to the stratum

## Bias, costs and consequences

- There is a time/human resources cost from planning and preparing the design
- Financial cost to the treatment and implementation
- Risk of bias due to intervention
- Complexities in using the data

Auxiliary essential for all of these

# Measures of representativeness

2 types of indicator of effectiveness

Survey based indicator

- R indicator + others
- Coefficient of variation

Evaluates  
representativeness of the  
survey as a whole

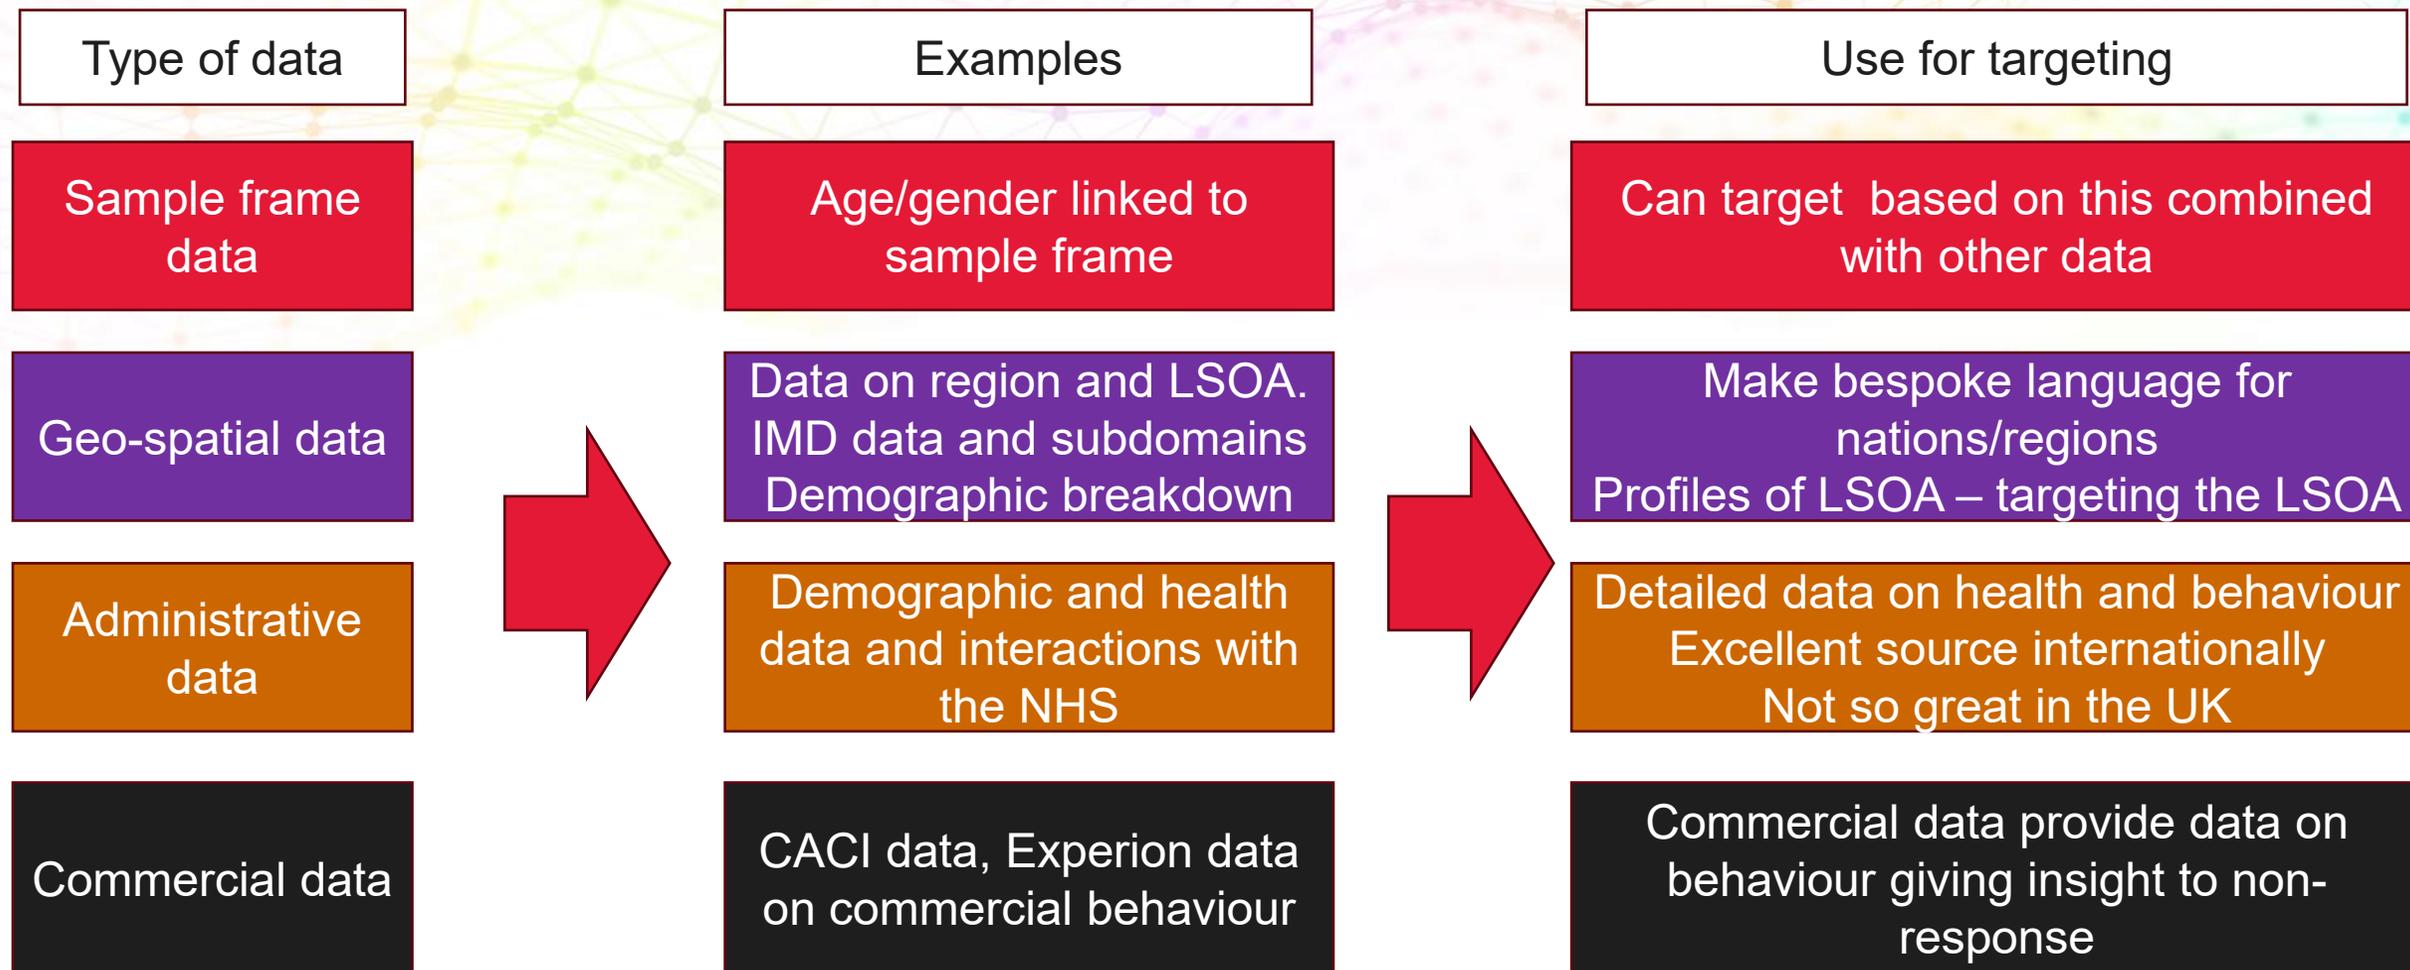

Variable or category  
based indicator

- Partial R-indicator

Evaluates  
representativeness with  
respect to 1 variable

Require good auxiliary  
data

# Non-survey data and its value

# Criteria for selecting variables from non-survey data

Two key dimensions on which variables are judged

Variables should be correlated with key outcomes and participation

Maximises how much of the variation in the key outcomes being explained

Intuition and consideration of correlation coefficients are key here

Variables should not be collinear with each other

Maximises the breadth of the variance in the key outcome being explained

Use previous experience, research and data to understand the best model

# 2 ways of targeting

## Subgroup targeting

Use past experience/intuition

Data used purely to identify strata within the sample

Most often used in UK  
Many examples – Generations and Gender Survey

## Data based targeting

Classify strata based on model of response propensity

Data used for stratification and selection for intervention

Used in TLFS, DESNZ public attitudes tracker

# Spectrum of interventions

Fieldwork role  
out

Invitation  
language

Follow up  
reminders

Knock to  
nudge

Differential  
incentives

Different  
modes

Role out  
fieldwork to  
lowest  
propensity  
parts of  
sample first

Change the  
language of  
invitation based  
on propensity  
or region

Issue more  
follow up  
reminders to  
higher non-  
response  
propensity  
people

In-person  
contact to  
help  
complete a  
CAWI  
survey

Allocate a  
greater or  
lesser  
incentive to  
different  
strata

Allocate a  
CAWI mode  
to some  
strata and a  
CAPI/CATI  
mode to  
others

Millenium  
Cohort Study

Understanding  
Society

Community  
Life Survey

TLFS

Children of  
the 2020s  
study

Dutch Labour  
Force Survey

# Sequencing, dosage and costs

---

Questions    When should the intervention be applied?

---

What is the appropriate dosage of the intervention?

---

How should we minimise the cost of the intervention?

---

# Optimisation approaches to adaptive design

## Trial and error approach

Use practitioner intuition with only a rough guide on trying to keep costs within a budget – Most UK examples – only relies on non-survey data to administer intervention (Schouten and Shlomo 2017)

## Stopping rules

Select a point at which the targeting will stop (Wagner 2010, Rao et al. 2008) – e.g. a particular response rate from a stratum or a particular coefficient of variation – Stopping rule depends on a particular variable derivable from non-survey data

## Propensity based prioritisation

Develop a model of non-response and apply intervention to lower propensity groups (Peytchev et al 2018, Wagner 2013)

## Mathematical optimisation

Use a mathematic procedure to ensure that the application of incentives is optimised to a budget constraint so as to maximise a particular quality (e.g. coefficient of variation) (van Berkel 2022)

# Recommendations

## Policymaker

- Access to better register data in the UK would be useful
- Facilitating access to linked data
- Training in strengths and weaknesses of adaptive design

## Survey agencies

- Significant opportunity for adaptive design with what is currently extant in the UK
- Opportunities to use more advanced approaches like mathematical optimisation and Bayesian Adaptive Design
- More training opportunities on how to implement adaptive designs
